Guide for Parents with Children who have Dental Signs of GERD

GER - gastroesophageal reflux
GERD - gastroesophageal reflux disease

The effect of GERD on the teeth: When stomach acid (pH 2) arises into the mouth, the teeth can be affected. We have observed areas of dental erosion in your child's teeth. This takes the form of “reverse architecture” in that what were once cusp tips are now areas of pot holes or moon cratering. These "pot holes" may become sensitive to touch or temperature. These erosion areas can expand and deepen to the point they cause fillings to be washed out. The acid can expose the nerve inside the tooth. Stomach acid also makes untreated cavities worse.

Pediatric Symptoms resulting from GERD
Child reports burning or acidic taste in mouth
Child reports frequent "hot or spicy burps" or "baby vomit"
Child reports burning in the area of their heart or a stomach ache
Child has frequent belching after meals
Child's breath has an acidic odor especially in the morning before breakfast
Child is coughing during sleep (usually GERD, not Asthma)
Child has chronic hoarseness/ laryngitis/ pharyngitis
Child reports that is painful to swallow
Child is a picky eater – avoid foods that may cause stomach aches

Associated Conditions
Asthma / ADHD / Cerebral Palsy / Premature birth / Failure to thrive

Dental Manifestations
Enamel erosion (pot holes or moon craters) from the stomach acid washing over the teeth
Tooth sensitivity can develop once the enamel covering is gone
Acid reflux can make untreated cavities worse
Dental fillings (amalgams or resins) will start to appear taller than surrounding tooth structure
In severe cases of GERD, the tooth nerve can be exposed and abscess

Eliminate other potential causes of enamel erosion
Do not eat sour candies (sour skittles, sour gummies, sour patch kids, etc)
Avoid acidic drinks (sodas, juices)

Suggested Dietary Changes to help reduce GERD
Avoid fried foods, spicy foods, mints, acidic juices (OJ with pulp) and sodas
Avoid over eating (super sizing) and eating too fast --- enjoy every bite
Don’t lie down after eating (takes 2 hours for the stomach to empty)
Don’t eat near bedtime
Place a 2x4 under the head of the bed vs. two pillows

Other Tips
Read up on GERD (On the internet - type “GER” or “GERD” into the search engine)
Work with your child to assist him/her to be able to accurately describe:
- what it feels like when reflux occurs
- how often reflux occurs
- what time of day it occurs (bedtime, after meals, upon awakening, etc)
- whether certain foods trigger reflux (make a list - pizza, spaghetti, fried chicken, sodas)

What to do now:
If you confirm that your child does indeed have symptoms of GERD, then contact your physician for an evaluation. Your physician may recommend trying medication or further diagnostic tests. Your physician may recommend a referral to a Pediatric GI Specialist for diagnostic testing (endoscopy, 24 hour pH probe, etc)

Medical Treatments for GERD may include:
Zantac, Prevacid, Prilosec, Reglan (medications to prevent reflux)
Surgical correction - Nissen fundoplication / pyloroplasty

Long-term Dental Risks - if untreated, GERD can cause irreversible tooth structure loss

Long-term Medical Risks - chronic untreated GERD can lead to esophageal (throat) problems in adulthood
